Join us at the Aeneas Solar Energy Society's 33rd ANNUAL NATIONAL SOLAR CONFERENCE on August 5-11, 2023, in Boulder, Colorado!

The Aeneas Solar Energy Society (ASES) is delighted to serve and advance the solar energy industry by bringing together national labs, installers, government officials, and enthusiasts in the solar and renewable energy industries to explore solutions, new technologies, and policies for a sustainable future.

NYSES members, their families and friends will receive 10% off registration.

Tennessee Valley Authority

The Tennessee Valley Authority, the nation's largest public power provider that sells its wind energy to utilities, is the latest to apply for funding through a competitive clean energy loan. TVA claims its new facility will help it achieve its net-zero carbon goals by 2050 and bring the Tennessee Valley region's economy into the clean energy future.

Russian attacks on Ukraine's energy grid have left it severely damaged. Now a growing number of Ukrainian hospitals, schools, and other critical buildings are racing to install solar panels and batteries to keep the lights on and avoid the dark days that can

- Webinars

Tennessee is home of Alcoa, the largest spike a boom in clean energy investment which will significantly reduce the state's carbon emissions. Tennessee's electricity sector is already relatively clean, with nuclear power and hydroelectric dams providing 43 percent and 16 percent, the EIA reported last year. Tennessee's clean energy projects increased investment in upstream oil and gas, which is expected to rise by 7% in 2023 in a short 2019 to 2022.

TVA claims its new facility will help it achieve its net-zero carbon goals by 2050 and bring the Tennessee Valley region's economy into the clean energy future.

At the annual Petroleum Climate Strategies (attended by officials from Russia, Saudi Arabia, and the United Arab Emirates), the oil and gas industry's leaders made it clear that they have no intention of reducing the production of the fossil fuels driving the climate disaster. Instead, they are betting on a future that will be very beyond the year 2050.

France has banned domestic short-haul (2.5 hours or less) flights when alternative exists, in a bid to cut aviation emissions. Critics claim the move is mere symbolism.

Tropical Cyclone Mocha, which struck Myanmar and Bangladesh at the start of May, was the strongest storm recorded in the Bay of Bengal in the satellite era, which began in the 1970s.

- Webinars

The Environmental Protection Agency proposed greenhouse gas emissions limits for coal, gas, and oil-fired power plants, with rules requiring reductions beginning in 2035 for coal-fired generators and 2032 for gas-fired units. The proposal would require coal-fired power plants that plan to operate after 2039 to capture 90% of their carbon pollution by 2039, while units with fewer than 40 years of life left would have to capture 90% of their carbon pollution by 2035. Gas-fired units that run 40% and 20-40% of annual gas fired capacity to be built, including 17-20% of capacity run from all clean hydrogen, from 2032 to 2038.

Wind

The four biggest Western makers of wind turbines—GE Renewable Energy, Siemens Gamesa, Vestas, and Nordex—have a combined market share of 70%. Each of the companies is also headquartered and has its largest manufacturing operations in Europe.

Russian invasion of Ukraine has disrupted the supply chains for wind turbine components, which has led to a significant increase in the cost of wind energy projects around the world. On the other hand, these supplier disruptions have created opportunities for new wind turbine companies to enter the market, as they can more easily source components from suppliers that have been affected by the supply chain disruptions.

The time between signing a contract with wind farm developers and the start of construction has increased from around 18 months in 2021 to about a 36 months in 2022, according to Vestas and its Vestas Offshore. Many factors are mostly locked in during that time, turbine makers are exposed to increasing costs for raw materials, components, and transportation. The prices of raw materials and components, inflation, higher interest rates and geopolitical tensions.

Batteries

The notion of battery swapping is dismissed by some as unworkable. The main difficulty: EV batteries are cumbersome and there's no industry standard design.

A California startup, Ample, dedicated to battery swapping, is introducing a new streamlined station that cuts the process to about five minutes, far less than the 30 minutes or more needed at public fast chargers. The startup has come up with a modular design that accommodates the different EV designs.

Environment/Climate

Human activities are undeniably altering the thermal structure of Earth's atmosphere. An analysis conducted by Lawrence Livermore National Laboratory (LLNL) scientists and colleagues for the first time demonstrates that extending "fingerprinting" techniques — used to identify the human effects on climate — to the mid-to-upper stratosphere (25-50 kilometers above Earth's surface) improves the detection of human effects on climate by a factor of five. The distinct patterns of CO2-driven temperature changes in these areas underscore the impossibility of natural causes explaining these shifts.

SC Connector, a freight-hauling vessel owned by the Norwegian company Sea-Cargo, passing beneath the Karmsund Bridge in Norway. The ship is equipped with two rotor sails manufactured by Finland-based Norsepower. The 38-yard-high rotors spin in the wind and help propel the vessel. They also can tilt to avoid obstacles overhead. *(Tor Nilssen/Sea-Cargo via AP)*

Maritime shipping produces nearly 3% of the world's carbon emissions. The International Maritime Organization (IMO), which regulates commercial shipping, wants to halve its greenhouse gas releases by midcentury.

To this end, the IMO is pursuing the creation of "green shipping" corridors on which through the application of modern technologies it will seek to unite marine fuel producers, vessel owners and operators, cargo owners and ports in a common effort.

Ports of Los Angeles and Shanghai formed a partnership last year. Other agreements are being negotiated and executed.

"The vision is that a container will leave a factory on a zero-emissions truck (in China)," said the executive director of the Port of LA. "It will arrive at the port of Shanghai, be loaded onto a ship by a zero-emissions cargo handling equipment unit and move across the Pacific Ocean on a vessel that emits zero carbon. Once it gets to Los Angeles, the reverse happens."

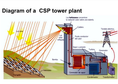
The Reads



Concentrating Solar Power **(CSP), technology to store thermal energy and to provide flexible, renewable energy, 24 hours a day,** 7 days a week, in regions with excellent direct solar resources. (By **Ignacio Martil,** *Professor of Electronics at the Complutense University of Madrid and member of the Spanish Royal Society of Physics)*

1. Concentrating Solar Power, the Other Major Renewable Energy Source

CSP plants are based on the use of mirrors that concentrate direct radiation from the sun onto a receiver filled with a fluid, usually thermal oil or molten salts. This fluid, called **heat transfer fluid, conducts heat to an exchanger where it is used to generate steam**. The steam is then directed under pressure to a turbine to move its blades and produce electrical energy, following a procedure similar to that used in conventional thermal power plants.

Broadly speaking, a CSP plant consists of three main units:

1. Solar collectors, are mirrors that reflect sunlight and concentrate it on a certain focus, converting solar energy into thermal energy.
2. A means of heat storage by means of water vapor or molten salts.
3. An electric power generator, which produces electricity via a turbine driven by steam that has been obtained from the conversion of solar radiation into heat.

- btvaopenmind.com/

2. Pros and Cons of Concentrated Solar Power

Attributes of CPS:

+ High energy efficiency (without the baggage of other high-efficiency sources(: 20% -40% vs. photovoltaics at 18% - 26% vs. nuclear at about 35% vs. natural gas combined cycle power plants at 45% to 50%.

+ Capacity to store energy produced: CSP plants can store thermal energy for 10 to 15 hours.

+ Flexible technology: CSP plants can stop feeding electricity to the grid and store the energy as heat, which can be used when needed, even at night. In this regard, CSP and photovoltaic solar energy are perfectly complementary.

- Need for high levels of irradiance: Only in places with high levels of solar irradiance – over 2,000 kWh/m^2/year, typical in southern Europe and northern Africa – can CSP plants be rolled out at competitive costs.

- High cost of electricity produced at CSP plants: While rapidly declining, the cost per kWh is substantially higher than for photovoltaics or wind power.

OPINION

Kirkland, CC-PDM-1.0 (via Wikimedia Commons)

Nuclear power can play a significant role in the search for energy resilience. *By Chad Cramer, Bill Lacivita, Daniel Pacthod, and Humayun Tai, McKinsey & Company*

The power sector has to decarbonize—at present, it accounts for about 30 percent of global emissions, and electricity demand could triple by 2050, driven by increasing electrification and economic growth.

Unlike renewables that offer an intermittent energy supply, nuclear has already demonstrated that it can provide 24/7 reliable and flexible power while using far less land than many renewables building more nuclear plants to provide reliable, always-on, zero-emissions power generation can seem like a simple decision. Yet in many important markets, including Europe, Japan, and the United States, public skepticism and hostility to doing so remains.

ICYMI / FYI

Potential paths to a fusion energy breakthrough

The light and heat that warms the Earth, powers its wind and water cycles, and grows its plant life comes from the sun — an enormous fusion reaction 94 million miles away.

Fusion energy is released when two atoms are forced together until they collapse into each other. It's the opposite process to the atom-splitting, or fission, that powers current forms of nuclear energy.

Tokamak - a magnetic donut: The dominant form of fusion uses a donut-shaped reactor wound around with magnetic coils — invented by Soviet scientists in the 1950s.

In 2021, the international team at EAST (the Experimental Advanced Superconducting Tokamak) ran at 120 million degrees Celsius, or 216 million degrees Fahrenheit, for an unprecedented 101 seconds — a runtime it increased by a factor of four in April.

Stellarator - twisting the donut: Another vestige from the cold war era, built in Princeton also in the 1950s. In theory, its twisted shape cancels out the instabilities in the circulating plasma, giving the magnetic "cage" that contains it far more stability than it would have in a tokamak. In 2018, the publicly funded Wendelstein 7-X fusion in Germany achieved a record three seconds of fusion.

Pulses and lasers - a pocket of plasma that is 10 million times denser than that in a tokamak is fused over a period 10 million times shorter. That was the approach seen in the landmark results from the Lawrence Livermore National Laboratory in December. In a historic first, the fusion reaction released more energy than had been applied in the process.

Tokamaks and stellarators can't generate electricity directly. Instead, their fusion reactions release a flood of radioactive neutrons, which batter the metal walls of their container, releasing heat that can be tapped to boil water for a steam turbine.

Fusion engine: The approach involves generating electricity directly from the fusion reaction itself. It takes advantage of the fact that magnetic fields and electric currents are two aspects of the same phenomenon — or more specifically, that disruptions in a magnetic field, caused in this case by a series of tiny fusion explosions, creates outpourings of electricity. Helion, a company in which Microsoft recently invested, committed to provide 50 MW of power by 2028, or face financial penalties.

The New York Solar Energy Society (NYSES)

a Chapter of the American Solar Energy Society (ASES)

prepares consumer knowledge handouts about energy conservation and renewable energy, and distributes Green Energy Times, a resource publication, to the public throughout eastern New York State. NYSES analyses legislation and state programs and visits with the staff of legislators in New York City, New York State, and Washington, DC. NYSES is a volunteer, grassroots, membership organization serving the children, families, engineers, architects, and teachers of New York State since 2007.

Our Mission:

To encourage the understanding and use of solar energy technologies through public outreach, to be a source of sound technical knowledge, and to provide a forum to address critical regional and state issues relating to solar energy solutions. We address the energy usage of all segments of society by increasing awareness of the benefits of renewables: solar, wind, biomass, geothermal ground source, tidal/wave energy, and energy efficiency.
